4. The Cell

- Overview of cellular structure and function.
- Introduction to prokaryotic and eukaryotic cells.

Understanding Biomolecules

Biomolecules are the building blocks of life. In Unit 1, students learn about the four primary classes of biomolecules: carbohydrates, lipids, proteins, and nucleic acids.

Carbohydrates

Carbohydrates are organic compounds composed of carbon, hydrogen, and oxygen. They are essential for energy storage and supply. Key points include:

- Monosaccharides: Simple sugars like glucose and fructose.
- Disaccharides: Formed from two monosaccharides (e.g., sucrose).
- Polysaccharides: Long chains of monosaccharides (e.g., starch, glycogen, cellulose).

Proteins

Proteins are made up of amino acids and play crucial roles in biological processes. Important aspects include:

- Structure: Proteins have four levels of structure (primary, secondary, tertiary, and quaternary).
- Function: Enzymes, structural components, transport, and signaling.

Lipids

Lipids are hydrophobic molecules that serve various functions, including:

- Energy storage: Fats and oils.
- Membrane formation: Phospholipids compose cell membranes.
- Signaling: Steroids act as hormones.

Nucleic Acids

Nucleic acids, such as DNA and RNA, are vital for genetic information storage and transfer. Key points include:

- Structure: Composed of nucleotides, which include a sugar, phosphate group, and nitrogenous base.
- Function: DNA stores genetic information, while RNA plays a role in protein synthesis.

The Importance of Water

Water is essential for life, and its properties significantly influence biological systems. Understanding these properties is crucial for students in AP Biology.

Properties of Water

1. Cohesion and Adhesion

- Cohesion: Water molecules are attracted to each other. This property contributes to surface tension.
- Adhesion: Water molecules can also adhere to other substances, which helps in capillary action.

2. High Specific Heat

- Water can absorb significant amounts of heat without a large increase in temperature, allowing organisms to maintain stable internal conditions.

3. Universal Solvent

- Water's polarity allows it to dissolve many substances, facilitating biochemical reactions.

Chemical Bonds and Reactions

Understanding chemical bonds is crucial for grasping how biomolecules interact in biological systems.

Types of Chemical Bonds

- Ionic Bonds: Formed through the transfer of electrons; one atom becomes positively charged, and the other becomes negatively charged.
- Covalent Bonds: Formed when atoms share electrons.
- Hydrogen Bonds: Weak attractions between polar molecules, significant in water and biological macromolecules.

Enzymes and Biochemical Reactions

Enzymes are proteins that catalyze biochemical reactions, lowering the activation energy required for reactions to proceed. Key concepts include:

- Active Site: The region of an enzyme where substrate molecules bind.
- Enzyme-Substrate Complex: The temporary complex formed when an enzyme binds to its substrate.

Cell Structure and Function

Unit 1 introduces students to the basic structures and functions of cells.

Prokaryotic vs. Eukaryotic Cells

- Prokaryotic Cells: Simple, smaller cells without a nucleus or membrane-bound organelles. Example: bacteria.
- Eukaryotic Cells: More complex, larger cells with a nucleus and membrane-bound organelles. Examples: plant and animal cells.
