Types of Series in Calculus 2

Understanding the different types of series is foundational in calculus 2. A series is the sum of the terms of a sequence and can be finite or infinite. The primary focus in Calculus 2 is on infinite series, which can be classified into various types based on their properties and behavior.

Geometric Series

A geometric series is a series where each term is obtained by multiplying the previous term by a constant ratio r . The general form of a geometric series is:

$$\sum_{n=0}^{\infty} ar^n$$

This series converges if and only if the absolute value of the ratio $|r| < 1$, and the sum is given by:

$$S = a / (1 - r)$$

Arithmetic Series

Although arithmetic series are less common in infinite series analysis, they are sequences with a constant difference between terms. The sum of the first n terms of an arithmetic series is:

$$S_n = n/2 (a_1 + a_n)$$

Infinite arithmetic series diverge since the terms do not approach zero.

P-Series

P-series take the form:

$$\sum_{n=1}^{\infty} 1/n^p$$

The convergence depends on the value of p :

- Converges if $p > 1$
- Diverges if $p \leq 1$

Alternating Series

Alternating series have terms that alternate in sign, usually expressed as:

$$\sum_{n=1}^{\infty} (-1)^{n-1} a_n$$

These series may converge conditionally or absolutely, depending on the behavior of a_n .

Tests for Convergence

Determining whether an infinite series converges or diverges is a critical skill in Calculus 2. Several tests help analyze series behavior, each applicable under different conditions. This section summarizes the most important convergence tests included in the calculus 2 series cheat sheet.

Divergence Test

Also called the n th-term test, this is the simplest test. If the limit of the terms a_n as n approaches infinity is not zero, the series diverges. Formally:

$$\lim_{n \rightarrow \infty} a_n \neq 0 \Rightarrow \sum a_n \text{ diverges}$$

Integral Test

This test applies to series with positive, continuous, and decreasing terms. It compares the series to an improper integral:

If $\int_1^{\infty} f(x) dx$ converges, then $\sum a_n$ converges, where $a_n = f(n)$.

Comparison Test

The comparison test involves comparing the given series to a known benchmark series:

- If $0 \leq a_n \leq b_n$ and $\sum b_n$ converges, then $\sum a_n$ converges.
- If $0 \leq b_n \leq a_n$ and $\sum b_n$ diverges, then $\sum a_n$ diverges.

Ratio Test

Widely used for series involving factorials or exponentials, the ratio test uses the limit:

$$L = \lim_{n \rightarrow \infty} |a_{n+1} / a_n|$$

- If $L < 1$, the series converges absolutely.
- If $L > 1$ or $L = \infty$, the series diverges.
- If $L = 1$, the test is inconclusive.

Alternating Series Test

For alternating series where terms decrease in magnitude and approach zero, this test confirms convergence. Specifically, if:

- $a_{n+1} \leq a_n$ for all n
- $\lim_{n \rightarrow \infty} a_n = 0$

Then the series converges.

Power Series and Radius of Convergence

Power series are infinite series of the form $\sum c_n(x - a)^n$, where c_n are coefficients and a is the center of the series. They are fundamental in representing functions as infinite polynomials and play a central role in calculus 2.

Definition of a Power Series

A power series centered at a is expressed as:

$$\sum_{n=0}^{\infty} c_n(x - a)^n$$

The variable x can vary within a specific interval where the series converges.

Radius and Interval of Convergence

The radius of convergence R defines the distance from the center a within which the power series converges:

- For $|x - a| < R$, the series converges absolutely.
- For $|x - a| > R$, the series diverges.
- At the boundary points $|x - a| = R$, convergence must be tested separately.

Finding the Radius of Convergence

The radius of convergence can be found using the ratio or root test applied to the series coefficients:

Ratio test approach:

$$R = 1 / \limsup_{n \rightarrow \infty} |c_{n+1} / c_n|$$

Root test approach:

$$R = 1 / \limsup_{n \rightarrow \infty} |c_n|^{1/n}$$

Taylor and Maclaurin Series

Taylor and Maclaurin series provide powerful tools to approximate and represent functions as infinite sums of polynomials. They are extensively covered in any calculus 2 series cheat sheet due to their practical importance.

Taylor Series

The Taylor series of a function $f(x)$ centered at a is given by:

$$f(x) = \sum_{n=0}^{\infty} (f^{(n)}(a) / n!) (x - a)^n$$

Here, $f^{(n)}(a)$ denotes the n th derivative of f evaluated at a . This expansion approximates $f(x)$ near a .

Maclaurin Series

A special case of the Taylor series centered at zero ($a = 0$) is the Maclaurin series:

$$f(x) = \sum_{n=0}^{\infty} (f^{(n)}(0) / n!) x^n$$

This series is frequently used due to its simplicity and wide applicability.

Remainder Term and Approximation Accuracy

The difference between the actual function and its n th-degree Taylor polynomial is called the remainder or error term, which can be estimated using Lagrange's form of the remainder:

$$R_n(x) = (f^{(n+1)}(\xi) / (n+1)!) (x - a)^{n+1}, \text{ where } \xi \text{ is between } a \text{ and } x.$$

Estimating this remainder helps assess the accuracy of the approximation.

Common Series Expansions

Several standard functions have well-known series expansions that are often referenced in a calculus 2 series cheat sheet. Familiarity with these expansions is vital for solving problems involving series and approximations.

Exponential Function

The exponential function e^x has the Maclaurin series expansion:

$$e^x = \sum_{n=0}^{\infty} x^n / n!$$

This series converges for all real numbers x .

Sine and Cosine Functions

The sine and cosine functions have alternating series expansions:

- $\sin x = \sum_{n=0}^{\infty} (-1)^n x^{2n+1} / (2n+1)!$

- $\cos x = \sum_{n=0}^{\infty} (-1)^n x^{2n} / (2n)!$

Both series converge for all real numbers.

Natural Logarithm

The natural logarithm can be expanded as a power series centered at 1:

$$\ln(1 + x) = \sum_{n=1}^{\infty} (-1)^{n+1} x^n / n$$

This series converges for $-1 < x \leq 1$.

Binomial Series

The binomial series generalizes the expansion of $(1 + x)^k$ for any real exponent k :

$$(1 + x)^k = \sum_{n=0}^{\infty} (k \text{ choose } n) x^n$$

Where the generalized binomial coefficient is defined as:

$(k \text{ choose } n) = k(k-1)(k-2) \dots (k-n+1) / n!$

This series converges for $|x| < 1$.
